

Supervised learning

Inteligencia Artificial en los Sistemas de Control Autónomo
Máster en Ciencia y Tecnología desde el Espacio

Departamento de Automática

Objectives

1. Extend supervised learning algorithms
2. Apply supervised learning to real-world problems

Bibliography

- Müller, Andreas C., Guido, Sarah. Introduction to Machine Learning with Python. O'Reilly. 2016

Table of Contents

1. Generalization, overfitting and underfitting
2. k-Nearest Neighbors
 - k-NN classification
 - kNN regression
 - Summary
3. Linear models
 - Ordinary least squares
 - Ridge regression
 - Lasso regression
 - ElasticNet
 - Linear models for classification
 - Summary
4. Naive Bayes Classifiers
 - Summary
5. Decision Trees
 - Summary
6. Ensembles of Decision Trees
 - Summary
7. Support Vector Machines
 - Kernelized Support Vector Machines
 - Summary
8. A
 - b
 - A: Summary
 - ARIMA

Generalization, overfitting and underfitting

Generalization: accurate predictions on unseen data

- i.e. there is no overfitting neither underfitting
- Depends on model complexity and data variability

(Source)

k-Nearest Neighbors

k-NN classification (I)

k-NN (k-Nearest Neighbors): Likely, the simplest classifier

- Given a data point, it takes its k closest neighbors
- Same prediction than its neighbors

k-NN does not generate a model

- The whole dataset must be stored

k uses to be an odd number (1-NN, 3-NN, 5-NN, ...)

k-Nearest Neighbors

k-NN classification (II)

k determines the model complexity

- Smoother boundaries in larger k values
- Model complexity decreases with k
- If k equals the number of samples, k -NN always predicts the most frequent class

How to figure out the best k ?

k-Nearest Neighbors

k-NN classification (III)

k-Nearest Neighbors

kNN regression (I)

k-NN regression

Given a data point

1. Take the k closest data points
2. Predict same target value (1-NN) or average target value (k-NN)

Performance is measured with a regression metric, by default, R^2

k-Nearest Neighbors

kNN regression (II)

k determines boundary smoothness

1. With $k = 1$, prediction visits all data points
2. With large k values, fit is worse

k-Nearest Neighbors

Summary

Hyperparameters	Advantages	Disadvantages
k	Simple	Slow with large datasets
Distance	Baseline	Bad performance with hundreds or more attributes
		No model
		Dataset must be stored in memory

Linear models

Linear model (I)

Linear model

$$y = a_0 + a_1x_1 + a_2x_2 + \dots + a_nx_n$$

for a single feature $y = a_0 + a_1x_1$, where

- a_0 is the intercept
- a_1 is the slope

Linear models assume a linear relationship among variables

- This limitation can be easily overcome
- Surprisingly good results in high dimensional spaces

Different linear models for regression

- The difference lies in how a_i parameters are learned

Linear models (II)

Several methods to fit coefficients

- Ordinary Least Squares (OLS)
- Generalized Least Squares (GSL)
- Weighted Least Squares (WLS)
- Generalized Least Squares with AR Covariance Structure (GLSAR)

Regularization: Term that penalizes complexity

- L_1 (Lasso regression)
- L_2 (Ridge regression)
- ElasticNet: L_1 and L_2

Lasso

$$\lambda \sum_j \beta_j^2$$

Ridge

$$\lambda \sum_j |\beta_j|$$

ElasticNet

$$\alpha \sum_j \beta_j^2 + (1 - \alpha) \sum_j |\beta_j|$$

Linear models

Algorithms

ARIMA (I)

AR: Autoregressive model

- Current observation depends on the last p observations
- Long term memory

AR(p)

$$X_t = c + \sum_{i=1}^p \phi_i X_{t-i} + \epsilon_t$$

MA: Moving Average model

- Current observation linearly depends on the last q innovations
- Short term memory

MA(q)

$$X_t = \mu + \epsilon_t + \theta_1 \epsilon_{t-1} + \dots + \theta_q \epsilon_{t-q}$$

ARMA model = AR + MA

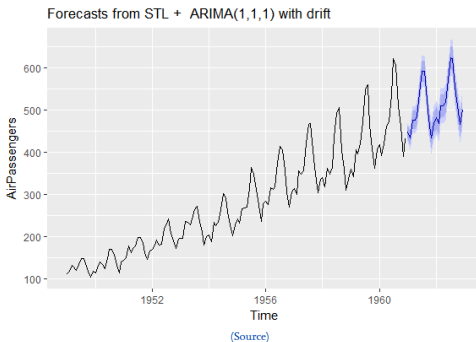

- ARMA(p, q): Two hyperparameters, p and q

Algorithms

ARIMA (II)

ARIMA = AR + i + MA (AR integrated MA)

- ARIMA(p, d, q)
- Three integer parameters: p, q and d (in practice, low order models)

autoarima: search over p, q and d
