### Table of Contents

- I. Clustering
  - Aplications
- 2. K-means
  - Overview
  - K-means algorithm
  - K-means limitations
  - Elbow's method
  - Application: Image segmentation
  - Application: for semi-supervised learning
  - K-means summary

- 3. Other clustering algorithms
  - GMM
  - DBSCAN
  - Summary
  - Agglomerative clustering
  - Agglomerative clustering: Summary
- 4. Anomaly detection
- 5. Dimensionality reduction
  - PCA

# Clustering

K-means, agglomerative clustering, DBSCAN and GMM

# Clustering

# Applications

Set of unsupervised techniques that identify groups of data (named clusters)

• No universal definition of cluster: Centroid, medoid, dense regions, etc

#### Applications

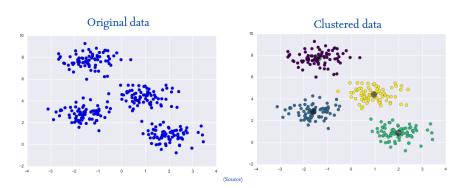

- Customer segmentation
- Data analysis
- Dimensionality reduction
- Anomaly detection
- Semi-supervised learning
- Search engines
- Image segmentation

#### Main algorithms

• K-means, DBScan, GMM, hierarchical clustering, EM, ...

#### Overview

In k-means, clusters are identified by a centroid

## K-means algorithm (I)

# K-means algorithm

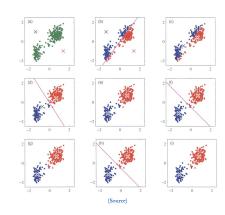

1. Set k random centroids

K-means 00000000

- 2. Assign each data point to its closest centroid
- 3. Recompute centroids
- 4. Go to 2 until no point reassignment

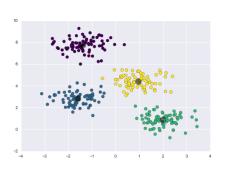

#### k is an hyperparameter

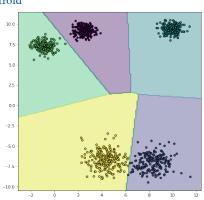

Number of clusters

## K-means algorithm (II)

### New data points are assigned to its closest centroid

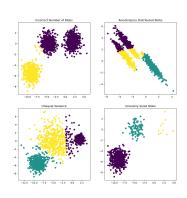

### K-means limitations

#### K-means can fail in several conditions

- Incorrect number of clusters
- Different clusters variance
- Non-spheric clusters  $\Rightarrow$  normalization

(Source)

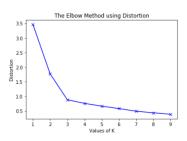

### Elbow's method

#### Election of k

- Not a problem when domain information is available
- ... that is rarely the case

#### Elbow's method

- I. Select K = 1, ..., n
- 2. Visualize performance for each k
- 3. Choose K where metric stabilizes

#### Performance measures

- Inertia: mean squared error between each instance and its closest centroid
- Silhouette:  $(b a)/\max(a, b)$ , where a mean intra-cluster distance, and b is the mean nearest-cluster distance

# Application: Image segmentation

(Source)

# Application: Clustering for semi-supervised learning

Semi-supervised learning: Only a subset of the dataset is labeled

- Supervised and unsupervised learning
- Quite common in real-world applications (labels use to be expensive)

f1	$f_2$		fn	Υ
$\mathfrak{a}_{1,1}$	$\mathfrak{a}_{2,1}$	• • •	$\mathfrak{a}_{\mathfrak{n},1}$	γ1
$\mathfrak{a}_{1,2}$	$\mathfrak{a}_{2,2}$	• • •	$\mathfrak{a}_{\mathfrak{n},2}$	
$\mathfrak{a}_{1,3}$	$\mathfrak{a}_{2,3}$	• • •	$\mathfrak{a}_{\mathfrak{n},3}$	
$\mathfrak{a}_{1,4}$	$\mathfrak{a}_{2,4}$	• • •	$\mathfrak{a}_{\mathfrak{n},4}$	γ4
$\mathfrak{a}_{1,5}$	$\mathfrak{a}_{2,5}$	• • •	$\mathfrak{a}_{n,5}$	

### Label propagation

- 1. Obtain k clusters
- Get a representative instance of each cluster (medoid) measuring the distance to the centroid
- 3. Label the members of each cluster with its medoid's label

# K-means: Summary

Hyperparameters	Advantages	Disadvantages
	Fast	Simple shapes
k	Few hyperparameters	Determine k
	Scalable	Random initialization

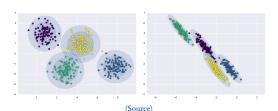

## Gaussian Mixure Model (GMM) (I)

#### GMM is a generative clustering algorithm

• Assumes data coming from a set of multidimensional gaussian distributions

GMM fits a set  $\{(\phi_i, \mu_i, \sigma_i)\}_{i=1,...,k}$ 

- $\bullet$   $\phi$  is a weight
- $\mu$  is a multidimensional mean
- $\sigma$  is a covariance matrix
- k is the number of clusters (hyperparameter)

### Gaussian Mixure Model (GMM) (II)

Gaussian parameters are fit with the Expectation-Maximization (E-M) algorithm

• E-M is a generalization of K-means

## Expectation-Maximization algorithm

- 1. Init parameters randomly
- 2. Expectation step: Assign each instance to a cluster
  - Assignment is probabilistic
- 3. Maximization step: Update cluster parameters
  - Each cluster is updated using all the data
  - Instances contribution to a cluster parameters is weighted by the probability that it belongs to it
- 4. Go to 2

GMM can be seen as a fuzzy clustering algorithm

Gaussian Mixure Model (GMM) (III)

Gaussian parameters are fit with the Expectation-Maximization (E-M) algorithm

• E-M is a generalization of K-means

## Expectation-Maximization algorithm

- 1. Init parameters randomly
- 2. Expectation step: Assign each instance to a cluster
  - Assignment is probabilistic
- 3. Maximization step: Update cluster parameters
  - Each cluster is updated using all the data
  - Instances contribution to a cluster parameters is weighted by the probability that it belongs to it
- 4. Go to 2

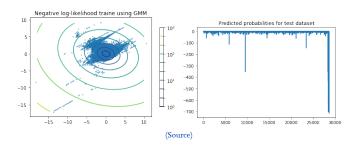

GMM can be seen as a fuzzy clustering algorithm

Gaussian Mixure Model (GMM) (IV)

#### GMM provides a probability of an instance to belong to a cluster

- This can be used to detect anomalies
- Just assign a probability threshold

**GMM: Summary** 

Hyperparameters	Advantages	Disadvantages
Number of clusters	Probabilistic clustering	Number of clusters
Covariance matrix type	Generative model	Gaussian data
	Anomaly detection	Sensitive to outliers

# Other clustering algorithms DBSCAN (I)

#### DBSCAN: Density-Based Spatial Clustering of Applications with Noise

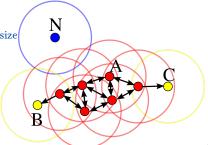

- Identifies high density regions (dense regions) in feature space
- Asumtion: Clusters form dense regions separated by empty areas

#### Hyperparameters

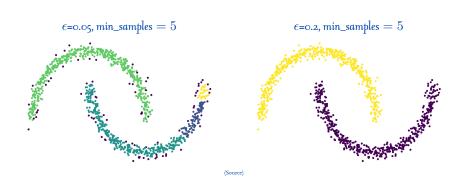

- $\bullet$   $\epsilon$ : Radius of a neighborhood
- min\_samples: Minumun cluster size

### Type of points

- Core instance
- Outliers

(Source)

# DBSCAN: Summary

Hyperparameters	Advantages	Disadvantages
$\epsilon$	No explicit number of clusters	Slower than K-means
min_samples	Scales relatively well	Clusters with different densities
	Almost deterministic	
	Robust to outliers	
	Anomaly detection	

# Agglomerative clustering (I)

## Agglomerative clustering

- 1. Initially, each instance forms a cluster
- 2. Merge the two most similar clusters according to a metric
- 3. Repeat 2 until a stop criterion is satisfied

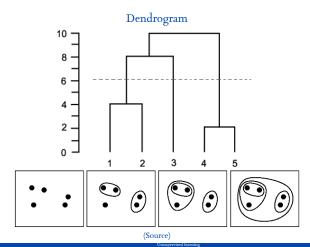

We need a similarity measure between two clusters

- Ward: Minimizes variance within merged clusters. Leads to equally sized clusters
- Average: Minimizes average distances between their points
- Complete: Minimizes maximun distance between their points

Agglomerative clustering (II)

Agglomerative clustering is a special case of hierarchical clustering

Agglomerative clustering: Summary

Hyperparameters	Advantages	Disadvantages
	Complex shapes Hierarchical clustering	
	Therarchical clustering	

Anomaly detection

# Anomaly detection

TODO

PCA and manifold learning

## Principal Components Analysis (I)

### Dimensionality reduction transforms data into more convenient representations

- Reduce data dimensionality
- Visualize multidimensional data

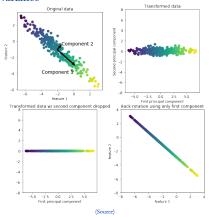

### Main algorithms

- Isomap
- T-distributed Stochastic Neighbor Embedding (t-SNE)
- Principal Components Analysis (PCA)

### Principal Components Analysis (II)

#### PCA maximizes data variance

### Principal Components Analysis (III)

Example: Hand-written digits recognition

- Images of hand-written digits
- 8x8 images (64 dimensions)
- 10 digits
- Classification problem
